AB Okadaic acid as well as other, structurally different, **inhibitors** of serine/threonine **phosphatases** 1 and 2A induce apoptosis in pituitary GH3 cells. Incubation with stepwise raised concns. of okadaic acid resulted in the isolation of cells that were increasingly less sensitive to the cytotoxic effect of this agent. After about 18 mo cells were selected that survived at 300 nM okadaic acid, which is about 30 times the initially lethal concentration This study revealed that a major pharmacokinetic mechanism underlying cell survival was the development of a P-glycoprotein-mediated multidrug resistance (MDR) phenotype. The increase in mRNA levels of the mdr1b P-glycoprotein isoform correlated with the extent of **drug resistance.** Functional assays revealed that increasing **drug resistance** was paralleled by a **decreased** accumulation of rhodamine 123, a fluorescent dye which is a substrate of mdr1-mediated efflux activity. Resistance could be abolished by structurally different chemosensitizers

of P-glycoprotein function like verapamil and reserpine but not by the leukotriene receptor antagonist MK571 which is a modulator of the multidrug resistance-associated protein (MRP). Okadaic acid resistance included cross-resistance to other cytotoxic agents that are substrates of mdr1-type P-glycoproteins, like doxorubicin and actinomycin D, but not to non-substrates of mdr1, e.g. cytosine arabinoside. Thus, functional as well as biochem. features support the conclusion that okadaic acid is a substrate of the mdr1-mediated efflux activity in rat pituitary GH3 cells. Maintenance of resistance after withdrawal of okadaic acid as well as metaphase spreads of 100 nM okadaic acid-resistant cells suggested a stable MDR genotype without indications for the occurrence of extrachromosomal amplifications, e.g. double minute chromosomes.

DT Journal
LA English
AB LoVo adenocarcinoma cells are fairly sensitive to cytostatic drugs, e.g. doxorubicin, but can develop **drug resistance** by expression of a P-glycoprotein-mediated MDR1 phenotype. LoVo cells respond with apoptosis to nanomolar concns. of okadaic acid and micromolar concns. of cantharidic acid. Interestingly, LoVoDx cells which had become about 10-fold less sensitive to doxorubicin by incubation in increasing concns. of this cytostatic drug were also less sensitive to the toxicity of okadaic acid. Resistance to both agents was lost or significantly **reduced** by incubation in drug-free medium for about 4 mo. On the other hand, LoVoDx cells did not lose responsiveness to the structurally different **phosphatase inhibitor** cantharidic acid but were about twofold more sensitive to the cytotoxic effect of this agent. Thus, MDR expression protects LoVo cells from the toxicity of **phosphatase inhibitors** that presumably are substrates of the P-glycoprotein, e.g. okadaic acid and its derivs. but not cantharidic acid, despite the fact that both agents are potent inducers of apoptotic cell death via ser/thr **phosphatase inhibition.**

DT Journal
LA English
AB Acquired **drug resistance** and drug toxicity are the main limitations to successful chemotherapy. The addition of modifiers is intended to increase drug sensitivity and to **decrease** systemic

toxicity. Modulation of the sensitivity of ovarian tumor cells to adriamycin by sodium butyrate, interferon-α and verapamil was investigated. First passage cultures of cells derived from the ascitic fluid of a clin. refractory ovarian carcinoma patient (BH) and an established ovarian tumor cell line (CAOV-3) were used. Chromosomal G-banding, lipid content and alkaline **phosphatase** activity were investigated. CA 125 and P-glycoprotein were shown by immunoperoxidase staining. P-glycoprotein function was demonstrated using rhodamine. Drug sensitivity was determined by the MTT method. Double minute chromosomes and a homogeneously staining region were found in Bh cells. CAOV-3 and BH were CA 125-pos. Most of BH and several CAOV-3 cells were P-glycoprotein-pos. The P-glycoprotein-transport system was active in BH and less so in CAOV-3 cells. Sodium butyrate increased lipid accumulation whereas interferon-α **decreased** alkaline **phosphatase** activity in CAOV-3 (50%). CAOV-3 were initially more sensitive to adriamycin than BH. Sodium butyrate potentiated the antiproliferative effect of low concns. of adriamycin in Bh while in CAOV-3 the effect was less pronounced. BH and CAOV-3 cells showed different sensitivity profiles to interferon-α. Addition of interferon to adriamycin resulted in an additive growth **inhibiting** effect in BH cells only. Verapamil, known to reverse multidrug resistance, potentiated the antiproliferative activity of adriamycin in BH, whereas in CAOV-3 its effect seemed additive.

AB The bladder carcinoma cell line J82-NVB was selected for resistance to the new vinca alkaloid navelbine. These cells possessed a non-MDR phenotype and were cross-resistant to vinca alkaloids and taxoids. Some morphol. differences between sensitive (J82) and resistant (J82-NVB) cells were observed J82 cells had a heterogeneous population morphol. with both epithelial and spindle shaped cells, while J82-NVB cells were almost all of the epithelial type. Vimentin intermediate filaments were less organized in J82-NVB than in J82 cells. Moreover, desmosomes were present in the membranes of J82-NVB cells but not in J82 cells. These findings suggest that J82 cells are poorly differentiated epithelial cells while J82-NVB cells possess some characteristics of a more differentiated epithelial cell line. After a two-week treatment with all-trans retinoic acid, all the cells became spindle shaped, vimentin filaments reappeared in the cytoplasm of J82-NVB cells and desmosomes disappeared from the membranes of these cells. These changes were accompanied by a decrease from 17 to 4.6 of the resistance factor of J82-NVB cells to navelbine. This decrease in resistance was concomitant with modifications of microtubules assembly regulation mechanisms. After navelbine treatment, microtubule reassembly occurred in resistant but not in sensitive nor in retinoic acid treated cells. Okadaic acid, a protein **phosphatase inhibitor**, **inhibited** microtubule reassembly in resistant cells, and 2-aminopurine, a protein kinase **inhibitor**, induced microtubule reassembly in sensitive cells after navelbine treatment. These findings show that microtubule reassembly after depolymn. is regulated by the kinase/**phosphatase** systems. A treatment with phorbol myristate acetate (PMA), a protein kinase C (PKC) agonist, induced the same morphol. modifications and resistance decrease as retinoic acid

treatment. A specific PKC **inhibitor** (Bisindolylmaleimide) prevented these PMA-induced morphol. modifications and resistance decrease in J82-NVB cells, showing that these effects were mediated by PKC. This study suggests that, in part by acting on some properties of the cytoskeleton, the differentiation modulator, retinoic acid, and the signal transduction modulator, phorbol myristate acetate, can decrease the resistance of J82-NVB cells to microtubule poisons.

AB Previous studies have demonstrated that human HL-60 myeloid leukemia cells differentiate in response to phorbol esters. This event is associated with induction of the c-jun early response gene and appearance of a monocytic phenotype. The present studies have examined the effects of vincristine-selected, multi-**drug resistance** on 12-O-tetradecanoylphorbol-13-acetate (TPA)-induced HL-60 cell differentiation. The results demonstrate that multi-drug-resistant HL-60 cells, designated HL-60/zinc, fail to respond to TPA with an increase in c-jun transcripts or other phenotypic characteristics of monocytic differentiation. By contrast, treatment of HL-60/zinc cells with okadaic acid, an **inhibitor** of serine/threonine protein **phosphatases**, increase c-jun transcription, growth arrest, and expression of the c-fms gene. Studies were also performed with an HL-60/zinc revertant (HL-60/zinc/R) line that has regained partial sensitivity to vincristine. The finding that HL-60/zinc/R cells respond to TPA with induction of a monocytic phenotype, but not c-jun expression, suggests that c-jun induction is not obligatory for monocytic differentiation. Other studies further demonstrate that the jun-B and fra-1 genes are induced by TPA in both HL-60/zinc and HL-60/zinc/R cells, whereas c-fos expression is attenuated in the HL-60/zinc line. Since TPA activates protein kinase C (PKC), the authors examined translocation of PKC from the cytosol to the membrane fraction. Although HL-60 and HL-60/zinc/R cells demonstrated translocation of PKC activity, this subcellular redistribution was undetectable in HL-60/zinc cells. Activity of the mitogen-activated protein kinase family with associated phosphorylation of c-Jun Y-peptide was markedly **diminished** in TPA-treated HL-60/zinc cells, but not in response to okadaic acid. Taken together, these findings suggest that vincristine resistance confers insensitivity to TPA-induced differentiation and can include defects in PKC-mediated signaling events and induction of jun/fos early response gene expression.

AB Resistance of human CCRF-CEM leukemic cells in tissue culture to 5-fluoro-2'-deoxyuridine (FdUrd)(I) [50-91-9] was examined following a single drug exposure (FS sublines). In two FS sublines generated by soft agar cloning of FdUrd sensitive cells in the presence of 1 nM FdUrd, the level of **drug resistance** was maintained at 22- to 30-fold following 1 mo growth in the absence of FdUrd. Characteristic of the FS sublines was a **decreased** accumulation and retention of free intracellular 5-fluoro-2'-deoxyuridine-5'-monophosphate (FdUMP) [134-46-3] averaging 3% of FdUrd sensitive cells, a more rapid rate of disappearance of free FdUMP and FdUMP-bound thymidylate synthase (EC 2.1.1.45) (5,10-methylenetetrahydrofolate:dUMP C-methyltransferase) [9031-61-2], and enhanced alkaline [9001-78-9] and acid phosphatase [9001-77-8] activities. There was no significant difference in the number of nucleoside transport sites per cell among the FS sublines and FdUrd-sensitive cells, indicating that the **decreased** accumulation of FdUMP in the resistant sublines was not the result of impaired FdUrd transport across the plasma membrane. The more rapid turnover of FdUMP-bound thymidylate synthase observed in the FS sublines was neither accompanied by a **decreased** stability of the thymidylate synthase-FdUMP-5,10-methylenetetrahydrofolate ternary complex, nor an enhanced rate of degradation of FdUrd to the less potent agent, 5-fluorouracil [51-21-8]. In addition, the growth rates of the 2 FS sublines were similar to that of FdUrd sensitive cells in medium containing hypoxanthine, methotrexate, and thymidine, indicating that there was no depletion of thymidine kinase (EC 2.7.1.21) (ATP:thymidine-5'-phosphotransferase) [9002-06-6] in the FS sublines. Apparently enhanced activities of acid and alkaline phosphatases, which influence the intracellular accumulation and retention of FdUMP, are important determinants of stable FdUrd resistance in CCRF-CEM cells.

AB Paclitaxel is a microtubule stabilizer and has been used as a promising chemotherapeutic agent for various human cancers, especially advanced ovarian and breast cancers. GL331 is a new semisynthetic podophyllotoxin compound developed to cope with the multiple **drug resistance** property evolved in cancer cells against its congener etoposide. We have found that both paclitaxel and GL331 can cause abnormal CDC 2 activation and subsequent apoptosis in human nasopharyngeal carcinoma (NPC) cell lines. Further analyses on two regulators of CDC 2, CDK 7 and CDC 25, in NPC cells demonstrated that paclitaxel caused an increase in CDK 7 kinase activity, while GL331 treatment elevated the CDC 25 **phosphatase** activity and caused the dephosphorylation of CDC 2 proteins on tyrosine-15 and threonine-14 residues, suggesting that paclitaxel and GL331 elicited distinct mechanisms leading to apoptosis. We further determined the cytotoxic effect and underlying mechanisms by combining paclitaxel with GL331. Our results reveal that the treatment with paclitaxel plus GL331 was less cytotoxic than the treatment with paclitaxel or GL331 alone. Both the activation of CDC 2 kinase and the induction of apoptosis were dramatically **inhibited** in NPC cells treated with 0.1 uM of paclitaxel and 1 uM of GL331 simultaneously. This antagonism is apparently associated with the phosphorylation of Mdr-1 and **decreased** intracellular level of paclitaxel induced by GL331.

AB The inability to give a safe dose of a drug that will **inhibit** tumor growth in the human patient is termed clinical **drug resistance.** It reflects the relative drug responsiveness in the same patient of the tumor and of the patient's normal tissue. The clinical tumor resistance is commonly equivalent to clinical host sensitivity and the ratio of these 2 factors, drug effect on tumor and drug toxicity to host, provide a ``therapeutic ratio'' that can be tipped toward clinical resistance by either **decreasing** host resistance or increasing tumor resistance. Resistance is related to the therapeutic aim, to the therapeutic aim, to the host tissues at risk, and to the species involved. There are several types of clinical **drug resistance**, including innate or initial **drug resistance**; acquired, secondary or drug-induced resistance; and collateral resistance-acquired pari passu to a drug. Pharmacological bases for resistance include the lack of intake into the body, plasma protein binding, transmembrane transport, extracellular drug destruction, conversion to nucleosides, conversion to the aglycone, destruction of the nucleotide, and alteration of target enzyme. Resistance related to the following drugs is discussed: 6-mercaptopurine ribonucleoside, 6-methylthiopurine ribonucleoside, b-g-deoxythioguanosine, purine nucleotide **phosphatases**, 5-fluorodeoxyuridine, 5-fluorouridine, 1-b-D-arabinofuranosylcytosine, and 5-azacytidine. Mechanisms for circumventing clinical resistance include: **inhibition** of nucleoside phosphorylases, **inhibition** of cytidine deaminase, **inhibition** of purine nucleotide **phosphatases**, search for collateral sensitivity, use of selective combination, delivery to localized tumor areas, synthesized drug activated by catabolism, metabolic conditioning, metabolic activation, differential

genome activation, and specific sequential sensitivity enhancement. (59 refs)

AB The multiple drug-resistant human lymphoblastic leukemic cell, CEM/VLB100, had a **reduced** content of lysosomal enzymes and a greater relative rate of secretion of these enzymes, than the drug-sensitive cells CEM. The ability of CEM/VLB100 cells to accumulate (3H)vinblastine (VLB) was also greatly **reduced.** However, these effects were not seen in anthracycline- and vincristine-resistant HL60 cells or in CEM/VM-1 cells. Verapamil (VP; Boehr.Mannheim)

inhibited both the efflux of (3H)VLB and the secretion of lysosomal enzymes in CEM/VLB100 cells. In addition, secretion of N-acetylglucosaminidase (NAGA) and efflux of (3H)VLB by CEM/VLB100 cells was enhanced by NaCl.

ABEX The multiple drug-resistant human lymphoblastic leukemic cell, CEM/VLB100, had a **reduced** content of lysosomal enzymes compared with the drug-sensitive cells CEM. The levels of NAGA and beta-galactosidase were **reduced** by 77.1% and 81.1% in the CEM/VLB100 cells. However, these effects were not seen in anthracycline- and vincristine-resistant HL60 cells or in CEM/VM-1 cells. In addition, the rate of secretion of these enzymes was greater in CEM/VLB100 cells than in CEM cells. The % of the total NAGA and beta-galactosidase secreted over 30 min was 8.8% and 5.7%, respectively, in CEM cells, and 14.4% and 11.1%, respectively, in CEM cells. The amount and rate of release of acid **phosphatase** was low and did not vary between the cell lines. VP **inhibited** both the efflux of (3H)VLB and the secretion of lysosomal enzymes in CEM/VLB100 cells. VP at a concentration of 50 uM increased the accumulation of (3H)VLB by 3.4-fold and **inhibited** the secretion of NAGA by 50%. In addition, secretion of NAGA and efflux of (3H)VLB from CEM/VLB100 cells was enhanced by the addition of NaCl to the sucrose-containing medium. The development of multiple **drug resistance** in CEM cells did not alter the rate of synthesis of protein as a whole or of NAGA specifically. When CEM/VLB100 cells were incubated with (3H)VLB and fractionated on a Percoll gradient, the distribution of (3H)VLB among the various populations was similar to that of NAGA. Loss of enzyme and drug took place from the vesicular populations to varying degrees when cells were induced to secrete. (W114/SL)

AB Stress conditions associated with solid tumor microenvironments, including hypoxia, low pH, and nutrient deprivation have been long implicated in clinical intrinsic **drug resistance**, and associated with tumor cell resistance to topoisomerase II-directed agents in vitro. The involvement of two stress-induced signaling pathways, termed the unfolded protein response (UPR) and the ER-overload response (EOR), in **drug resistance** to the topoisomerase II-directed agent teniposide was investigated in EMT6 mouse mammary tumor cells.

Chemicals that disrupt ER function and physiological stress conditions cause the induction of glucose-regulated protein 78 kDa (GRP78) through the UPR pathway. Treatment of EMT6 cells with the serine/threonine kinase **inhibitor**, H7, **decreased** the basal level of GRP78 mRNA and **inhibited** the induction of GRP78 mRNA by brefeldin A, tunicamycin, and hypoxia. Treatment with the serine/threonine **phosphatase inhibitor**, okadaic acid, slightly increased both basal and brefeldin A-induced GRP78 mRNA levels, and counteracted the **inhibitory** effect of H7 on GRP78 mRNA expression. These results suggest that the UPR pathway/GRP78 induction involves a H7-sensitive serine/threonine kinase.

Disruption of ER function and exposure to hypoxia have also been shown to activate the nuclear transcription factor-κB (NF-κB) presumably through the EOR pathway. Treatment of EMT6 cells with brefeldin A, okadaic acid, and hypoxia all caused the activation of NF-κB. Transient transfection of EMT6 cells with the dominant-negative mutant of IκBα abolished okadaic acid and hypoxia-induced activation of NF-κB. It suggests that stress-induced NF-κB activation in EMT6 cells is mediated in part through the phosphorylation of serines 32 and 36 on IκBα. Furthermore, treatment with the proteasome **inhibitor**, MG-132, attenuated the activation of NF-κB in EMT6 cells treated with brefeldin A, okadaic acid, and hypoxia.

Using clonogenicity assays, the sensitivity of EMT6 cells to teniposide was determined in the presence of **inhibitors** of either the UPR or the EOR pathway. Blockade of the UPR pathway/GRP78 induction by H7 did not reverse BFA-induced resistance to teniposide. In contrast, **inhibition** of the EOR pathway/NF-κB activation

by MG-132 reversed stress-induced resistance to teniposide. Taken together, these results suggest that stress-induced resistance to teniposide is mediated by the activation of NF-κB rather than by the induction of GRP78.

AB Hypoxia or low oxygen availability is commonly experienced by cancer cells within solid tumors. It may also be encountered by malignant cells during their invasion through extracellular matrix in the early stages of metastasis. Hypoxia increases radiation and **drug resistance** of the tumor cells thus impeding the efficient treatment of cancer. It is clear that a better understanding of the effects of hypoxia on cancer cells and the underlying mechanisms involved in hypoxia-induced cell changes will provide knowledge needed for the rational design of cancer therapies to reverse hypoxia induced tumor cell resistance.

The goal of this study was to investigate the effects of hypoxia on two major characteristics of cancer cells--their proliferative ability and invasive potential. We present evidence that hypoxia does not **inhibit** invasion of four different ovarian carcinoma cell lines through the extracellular matrix as assessed by in vitro invasion assays. In addition, we show by zymography and immunoblotting that the detected proteolytic activity, which is due to matrix metalloproteinase MMP-2, is only partially **inhibited** under hypoxic conditions and is not rate limiting in the invasive process.

While invasiveness does not seem to be significantly affected by hypoxia, we found that a hypoxic environment **inhibits** proliferation of both ovarian carcinoma cell lines and a non-transformed cell line, CV-1P, leading to reversible G$\sb1$ cell cycle arrest. This G$\sb1$ arrest is concomitant with activation of the growth suppressive function of the retinoblastoma protein, pRB. The growth suppressive activity of pRB is controlled by its phosphorylation state which varies as a function of cell cycle phase. During G$\sb1$ the hypophosphorylated, active from predominates, while the hyperphosphorylated, inactive from accumulates during S, G$\sb2$ and M phase. We present evidence that hypoxia-induced pRB dephosphorylation results from synergy between an increase in specific pRB-directed **phosphatase** activity and p27 mediated **inhibition** of CDK2 activity. Concomitant with this induction of **phosphatase** activity and CDK2 **inhibition** is a dramatic increase in p27 protein abundance and a **decrease** in cyclin A and E protein levels. Immunoprecipitation studies revealed a high amount of p27 in association with cyclin-CDK2 complexes during hypoxia, while this association is undetectable under aerobic conditions. These data are consistent with the hypothesis that p27 **inhibition** of active cyclin-CDK2 complexes, in addition to lower amounts of cyclin A and E being available for active complex formation, can together result in the observed **decrease** in CDK2 activity during hypoxia. A model of the molecular mechanisms involved in hypoxia-induced cell cycle arrest is proposed.

FULL TEXT IS AVAILABLE IN THE ALL FORMAT
AB Collagen type XVIII (C18) belongs to a novel family of basement membrane collagens.1 The 184 aminoacid proteolytic fragment of the carboxyterminus of C18, endostatin, has been identified as a potent endogenous **inhibitor** of angiogenesis.2,3 The strategy to combat tumour growth and metastasis by **inhibition** of angiogenesis is attractive, since solid tumours depend on a vascular supply by newly formed blood vessels. Since endothelial cells, which are required for this process, are non-neoplastic, blocking their migration and proliferation should not lead to resistance. In mice, recombinant endostatin decreased the size of established primary and secondary tumours, and repetitive application of the peptide prevented recurrence.3
Previous Northern analysis showed almost exclusive expression of C18 RNA in the liver,1 but the cellular source of C18, from which endostatin derives, is unknown. To localise the C18/endostatin expressing cells in vivo, we carried out in-situ hybridisation4 with an RNA probe that encodes endostatin, combined with cell-specific immunostaining for vimentin, cytokeratin, and CD31 by the alkaline **phosphatase**-antialkaline **phosphatase** method, on three normal, four cirrhotic, and three neoplastic human livers. The RNA probe was generated by oligo(dT)-primed reverse transcription of human liver RNA with subsequent amplification by oligodeoxyribonucleotide primers corresponding to nucleotides 1483-1501 (CGA CCC ACA AGC CCA CCC G) and 2083-2062 (TCT CCG GCC ATC TGC ATC CAG G, endostatin-encoding region) of the published sequence.1 The amplicon was cloned into pZErO (Invitrogen, Leek, Netherlands) and its authenticity verified by restriction digests, DNA sequence analysis, and expression of the endostatin protein in Escherichia coli and baculovirus (not shown). Plasmids were linearised with XbaI or EcoRI restriction endonuclease, to generate sulphur- 35-labelled antisense or sense (control) run-off transcripts with T7 or SP6 RNA polymerase (BRL Gibco, Eggenstein, Germany). Transcripts were hybridised under high stringency, followed by RNase A digestion to remove mismatched sequences as described.4 For double labelling, immunohistology was done immediately before prehybridisation.4 Positive and negative controls included hybridisation with procollagen [alpha]1(I) and the sense (non-complimentary) endostatin probe, respectively.

FULL TEXT IS AVAILABLE IN THE ALL FORMAT
AB SAN DIEGO, March 26 /PRNewswire/ -- Ontogen Corporation, a drug discovery and development company, announced today that the United States (US) Patent and Trademark Office has issued a patent for the use of imidazoles as modulators that restore the sensitivity of multi-drug resistant cancer cells to chemotherapeutic agents. The patent covers methods of use and methods of manufacture pertaining to these novel pharmaceutical compositions added Dr. Barry E. Toyonaga, Ph.D., Chairman, President, CEO and Founder of Ontogen Corporation.
"By automating the medicinal chemistry process, Ontogen has discovered several new drug entities and is optimizing them for enhanced bioavailability, toxicity profiles and therapeutic efficacy," stated Dr. Toyonaga. "Our philosophy has been to create a strong pharmaceutical patent portfolio which protects bioactive substances and their uses, in addition to the hardware and software that we have patented. Ontogen has

shown measurable progress in moving compounds for our three corporate partners into pre-clinical trials and beyond. Now Ontogen is pursuing its own corporate research in cancer multi- drug resistance."
"This recently issued patent further bolsters Ontogen's intellectual property portfolio with 26 pending applications world-wide and 8 allowed or issued patents," added Frank S. Chow, Esq., Ontogen's Chief Patent Counsel. "Earlier, the company patented its work surrounding the **inhibition** of protein tyrosine **phosphatases** (PTPases) which protects Ontogen's non-phosphorus, non- peptide compound libraries from which several selective **inhibitors** to these enzymes are being evaluated in pre-clinical models."
